

# Constrained optimization: equality constraints

Lluís Garrido – lluis.garrido@ub.edu

November 2016

## Abstract

This laboratory is focused on constrained optimization and, in particular, on equality constraints. The constrained optimization problem will be easily transformed into an unconstrained optimization problem using Lagrange multipliers.

## 1 Equality constraints: KKT conditions

Let us begin with a summary of equality constrained optimization<sup>1</sup>.

Consider the problem of minimizing  $f(x)$  subject to the constraints  $g_i(x) = 0$  for  $i = 1 \dots m$ , where  $x \in R^n$ . Without any constraint,  $m = 0$ , the necessary condition for optimality is  $\nabla f(x) = 0$ .

Let us now examine the case where  $m = 1$ , that is, a single constraint. With the constraint  $g(x) = 0$ , we require that  $x$  lies on the graph of the (nonlinear) equation  $g(x)$ , see figure 1. Assume that  $x^*$  is the optimal point we are looking for. The steepest descent direction at  $x^*$ ,  $-\nabla f(x^*)$ , is orthogonal to the tangent of the contours of  $f$  through the point  $x^*$ . The same reasoning tells us that  $\nabla g(x^*)$  also is orthogonal to the curve  $g(x) = 0$  at  $x^*$ . Otherwise,  $x^*$  wouldn't be the optimum, see figure 1.

In addition,  $\nabla f(x^*)$  must be orthogonal to the tangent of the curve  $g(x) = 0$  at  $x^*$ . This can be easily demonstrated and here we just give an insight. Assume that  $x(t)$  is a curve  $\{x = x(t) : t_0 \leq t \leq t_1\}$  such that  $g(x(t)) = 0$ . In other words,  $x(t)$  is the feasible curve with respect to the constraint  $g(x) = 0$ . For  $t^*$ , we have that  $x(t^*) = x^*$ , the optimal value. Observe that  $f(x(t))$  has a minimum at  $t = t^*$ , that is, the derivative of  $f(x(t))$  with respect to  $t$  must vanish (i.e. be zero) at  $t = t^*$ . The derivative of  $f(x(t))$  with respect to  $t$  at  $t = t^*$  is

$$\left. \frac{d}{dt} f(x(t)) \right|_{t=t^*} = x'(t)^T \nabla f(x(t)) \Big|_{t=t^*} = x'(t^*)^T \nabla f(x^*)$$

The previous expression indicates us that  $\nabla f(x^*)$  must be orthogonal to the tangent of the curve  $g(x) = 0$  at  $x^*$ .

---

<sup>1</sup>The text written in this section has been obtained from Griva, I.; Nash, S.; Sofer, A., "Linear and nonlinear optimization", SIAM and <http://www.pitt.edu/~jrclass/opt/notes3.pdf>.

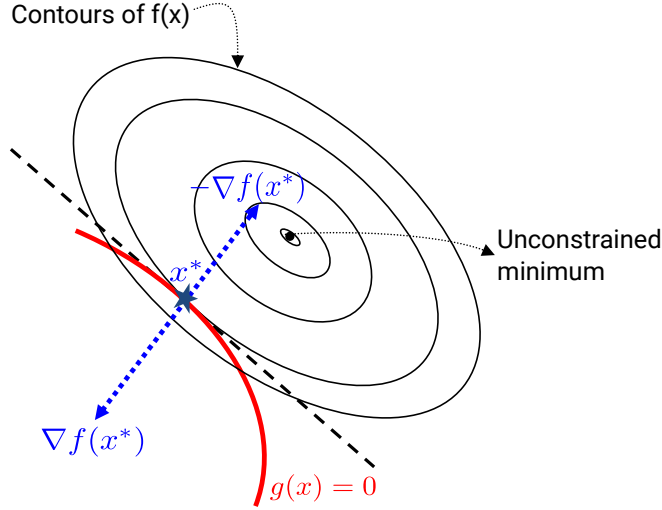

Figure 1: For a single constraint,  $m = 1$ , we seek a point  $x^*$  such that  $-\nabla f(x^*) = \lambda \nabla g(x^*)$ .

Therefore,  $-\nabla f(x^*)$  and  $\nabla g(x^*)$  must both lie along the same line. That is, for some  $\lambda \in \mathbb{R}$  we must have

$$-\nabla f(x^*) = \lambda \nabla g(x^*)$$

Thus, if  $x^*$  is a minimizer, the necessary condition reduces to

$$\nabla f(x^*) + \lambda \nabla g(x^*) = 0$$

For the general case, in which we have constraints  $g_i(x) = 0$  for  $j = 1 \dots m$ , the above necessary condition should hold for each constraint. Assuming that  $\nabla g_i(x^*)$  are linearly independent (or equivalently, the Jacobian matrix has full row rank), if point  $x^* \in \mathbb{R}^n$  is a minimizer for the equality constraint problem, it must satisfy the following necessary condition for some  $\lambda^* \in \mathbb{R}^m$ , that is

$$\nabla f(x^*) + \sum_{i=1}^m \lambda_i \nabla g_i(x^*) = 0 \quad g_i(x^*) = 0 \quad \forall i$$

The latter conditions are known as the **Karush-Kuhn-Tucker** (KKT) conditions.

## Example

Assume we want to minimize

$$f(x) = \frac{1}{2}x_1^2 + \frac{1}{2}x_2^2 - x_1x_2 - 3x_2 \quad \text{such that} \quad x_1 + x_2 = 3$$

Observe that  $m = 1$  (only one equality constraint) and that our constraint is  $g(x) = x_1 + x_2 - 3 = 0$ . The Lagrangian is

$$L(x, \lambda) = \left( \frac{1}{2}x_1^2 + \frac{1}{2}x_2^2 - x_1x_2 - 3 \right) + \lambda(x_1 + x_2 - 3)$$

where  $x \in R^3$  and  $\lambda \in R$ . The KKT conditions yield

$$\begin{aligned} \frac{\partial L}{\partial x_1} &= x_1 - x_2 + \lambda = 0 \\ \frac{\partial L}{\partial x_2} &= x_2 - x_1 - 3 + \lambda = 0 \\ \frac{\partial L}{\partial \lambda} &= x_1 + x_2 - 3 = 0 \end{aligned}$$

The minimizer can be found using the gradient descent. In this case, however, we have a set of linear equations and thus they can be easily solved. The minimizer is  $x_1^* = 0.75$ ,  $x_2^* = 2.25$ ,  $\lambda^* = 1.5$ .

### Exercise

We want to find the area of the largest rectangle that can be inscribed inside the ellipse

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$$

That is, we want to *maximize*  $f(x, y) = 4xy$  with  $g(x, y) = x^2/a^2 + y^2/b^2 - 1 = 0$ . You may use the gradient descent to obtain the solution.

## 2 An exercise: PCA analysis

Let us now focus on the Principal Component Analysis problem, that is,

$$\max_w w^T A w \quad \text{subject to} \quad w^T w = 1$$

where  $A$  is the covariance matrix of the considered data<sup>2</sup>.

There is a closed solution to the problem. For that issue consider the equivalent unconstrained problem

$$\max_w \frac{w^T A w}{w^T w}$$

An analytical solution to this problem can be found using  $\nabla_w = 0$ . Thus,

$$(Aw + (w^T A)^T) (w^T w)^{-1} - 2w^T A w (w^T w)^{-2} = 0$$

$$Aw - w^T A w (w^T w)^{-1} = 0$$

---

<sup>2</sup>The next text has been obtained from Oriol's Pujol notebooks of the Master

That is,

$$\frac{Aw}{w^T Aw} = \frac{w}{w^T w}$$

The solution of the former problem corresponds to the eigenvector of maximum eigenvalue. Figure 2 shows the Python's code that allows to perform such eigenvector analysis.

## Exercise

You are now asked to use the KKT conditions to see if you are able to obtain the same result as the one obtained with the closed solution. You may use the gradient descent to obtain the solution.

## Report

You are asked to deliver an *individual* report of the two exercises proposed in sections 1 and 2. Just explain each of the steps you have followed. If you want to include some parts of code, please include it within the report. Do not include it as separate files. You may just deliver the Python notebook if you want.

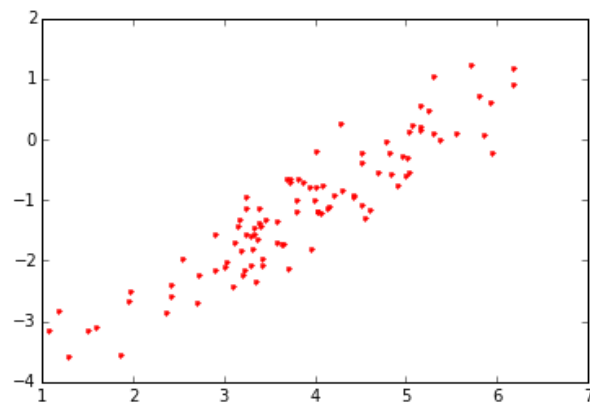

The deadline to deliver this report is December 6th at 3 p.m. (15h).

```
In [1]: import numpy as np
import matplotlib.pyplot as plt

%matplotlib inline

m1 = [4.,-1.]
s1 = [[1,0.9],[0.9,1]]
c1 = np.random.multivariate_normal(m1,s1,100)
plt.plot(c1[:,0],c1[:,1],'r.')
```

Out[1]: [`<matplotlib.lines.Line2D at 0x7fd3ba98d5d0>`]

```
In [2]: vaps,veps = np.linalg.eig(np.cov(c1.T))
idx = np.argmax(vaps)

plt.plot(c1[:,0],c1[:,1],'r.')
plt.arrow(np.mean(c1[:,0]),np.mean(c1[:,1]),
          vaps[idx]*veps[0,idx],vaps[idx]*veps[1,idx],0.5,
          linewidth=1,head_width=0.1,color='blue')
```

Out[2]: `<matplotlib.patches.FancyArrow at 0x7fd3baa21950>`

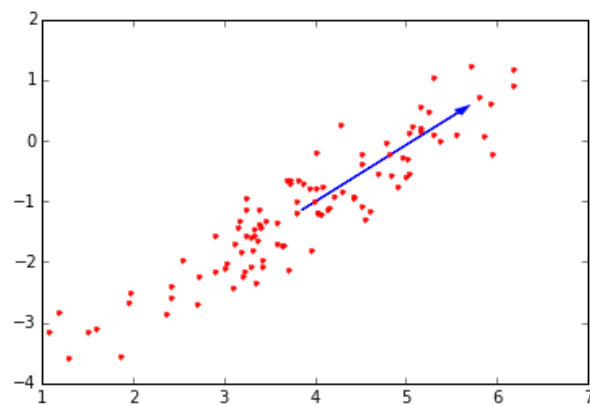

Figure 2: Python's code that allows to perform PCA analysis of a set of data. The red dots of the figure show the considered data, the blue arrow shows the eigenvector of maximum eigenvalue. Code thanks to Oriols' notebook.
